

# Temperature and Precipitation Data

CBRFC Stakeholder Forum  
July 31, 2012

## PRECIPITATION DATA– WHY IS THIS IMPORTANT ?

A direct input into the operational soil moisture & snow model

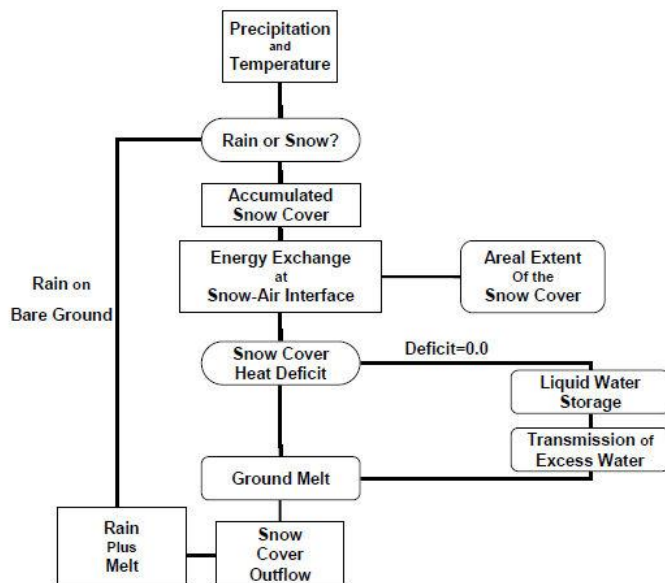

Primary Impacts:

Immediate runoff from rainfall events

Affects soil moisture conditions and seasonal volume forecasts

Combined with temperature to build snowpack in the model

## TEMPERATURE DATA– WHY IS THIS IMPORTANT ?

A direct input into the snow-17 operational model

Primary Impacts:

Determine precipitation type -> builds the snowpack

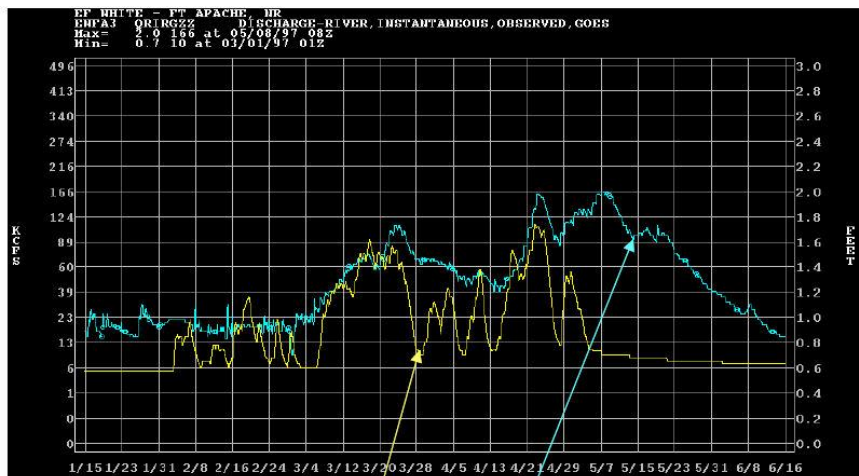

Energy and heat transfer properties:

Extent of snow cover

When the snowpack ripens in the spring

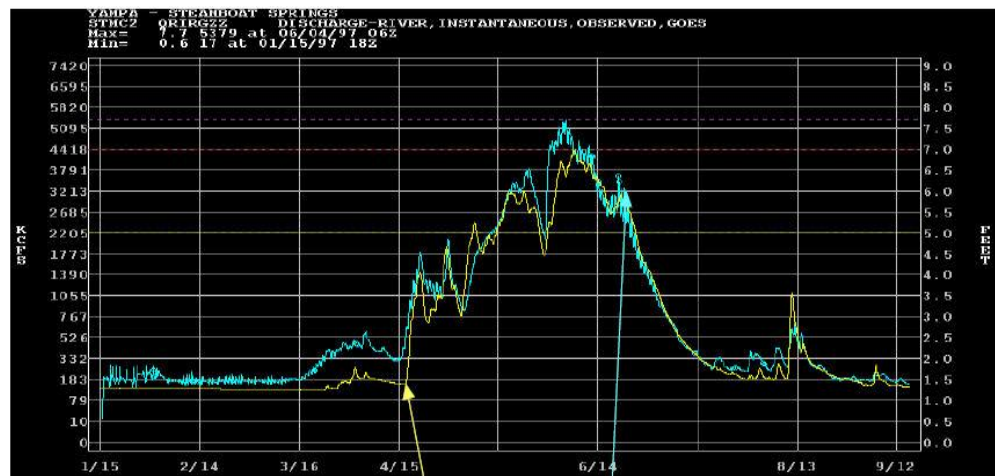

Process of melting the snowpack

# Selection of Temperature & Precipitation Stations Starts with Calibration of the Model

Simulated

Observed  
(blue)

## Data Site Requirements:

Relevant location to the river basin and sufficient historical period of record.

Must be stable through time (spent weeks verifying this through double mass analysis)

Maintain consistency between calibration and daily operations (use same data sites)

These requirements above tend to eliminate many candidates

## **DATA NETWORKS**

### **SOURCES (Precipitation)**

ALERT Networks (Automated Local Evaluation in Real Time-Radio)

GOES Data Collection Platforms (DCP) – includes Upper Colorado Network/RAWS/etc.

SNOTEL \*

Cooperators \*

CoCoRaHS (Community Collaborative Rain, Hail & Snow Network)

NEXRAD (Radar Products)

Satellite Derived

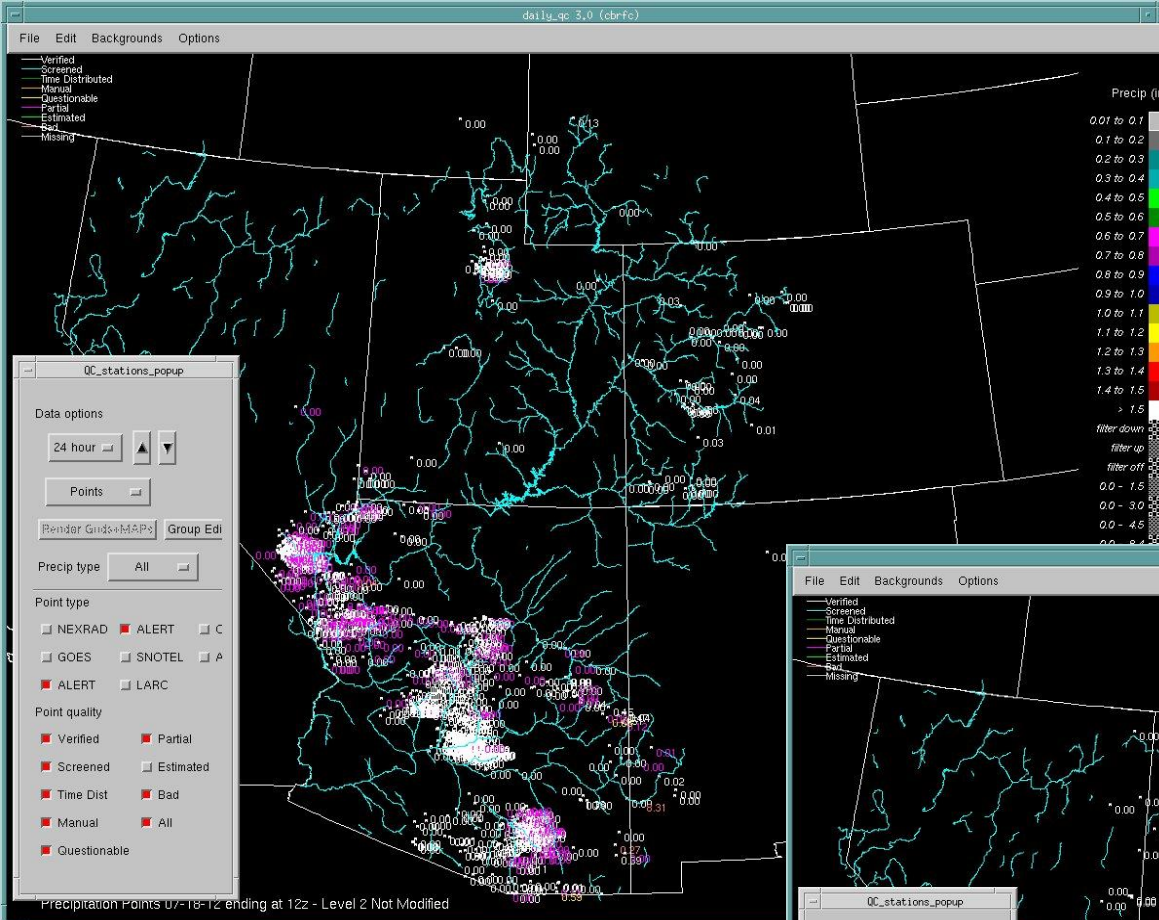

### **SOURCES (Temperature)**

GOES Data Collection Platforms (DCP) – includes Upper Colorado Network/RAWS/etc. \*

SNOTEL \*

Cooperators \*

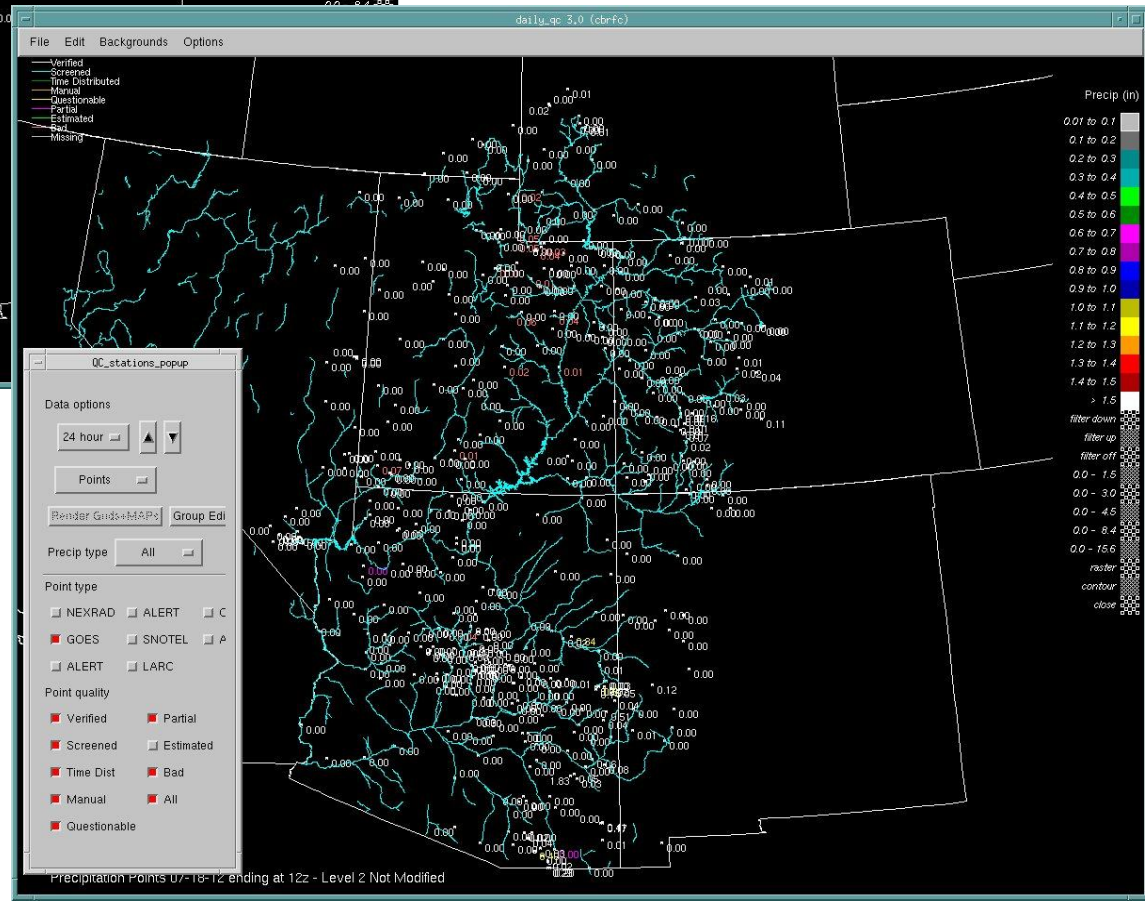

\* Data sources for model calibration

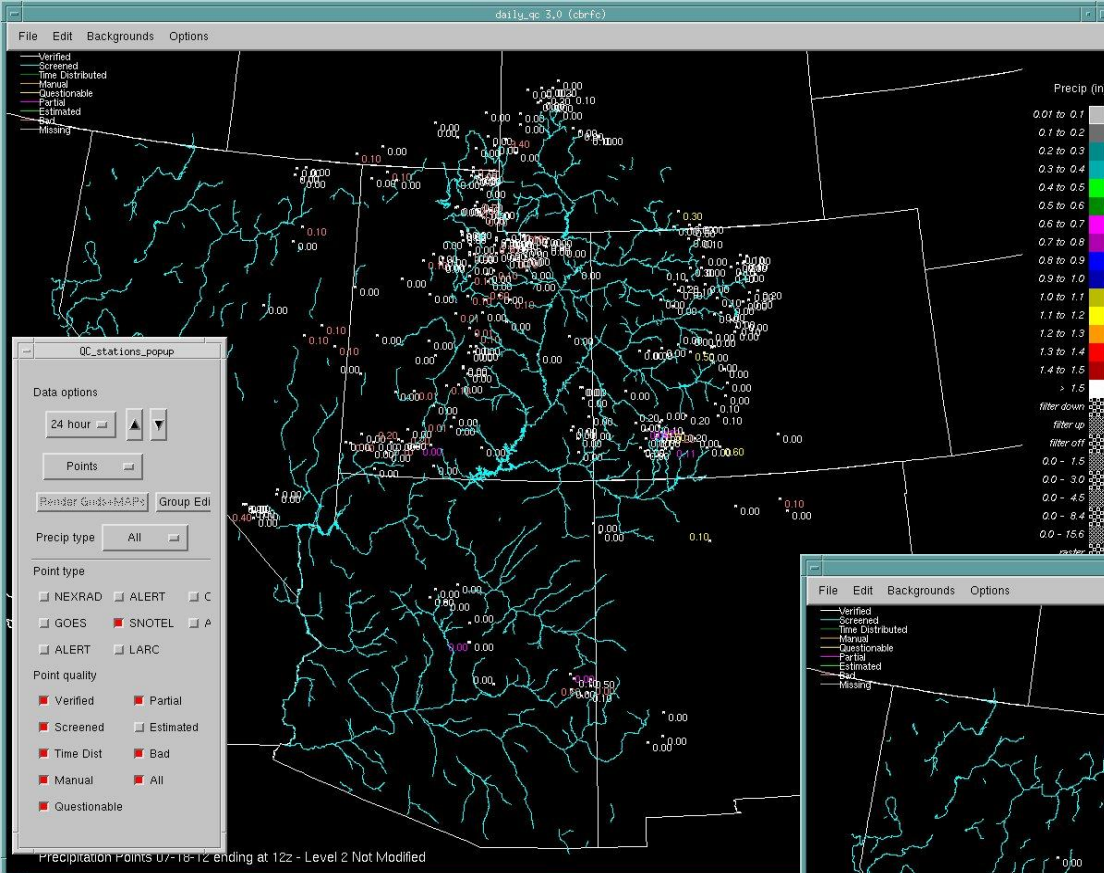

## ALERT & CoCoRaHS Precipitation Data

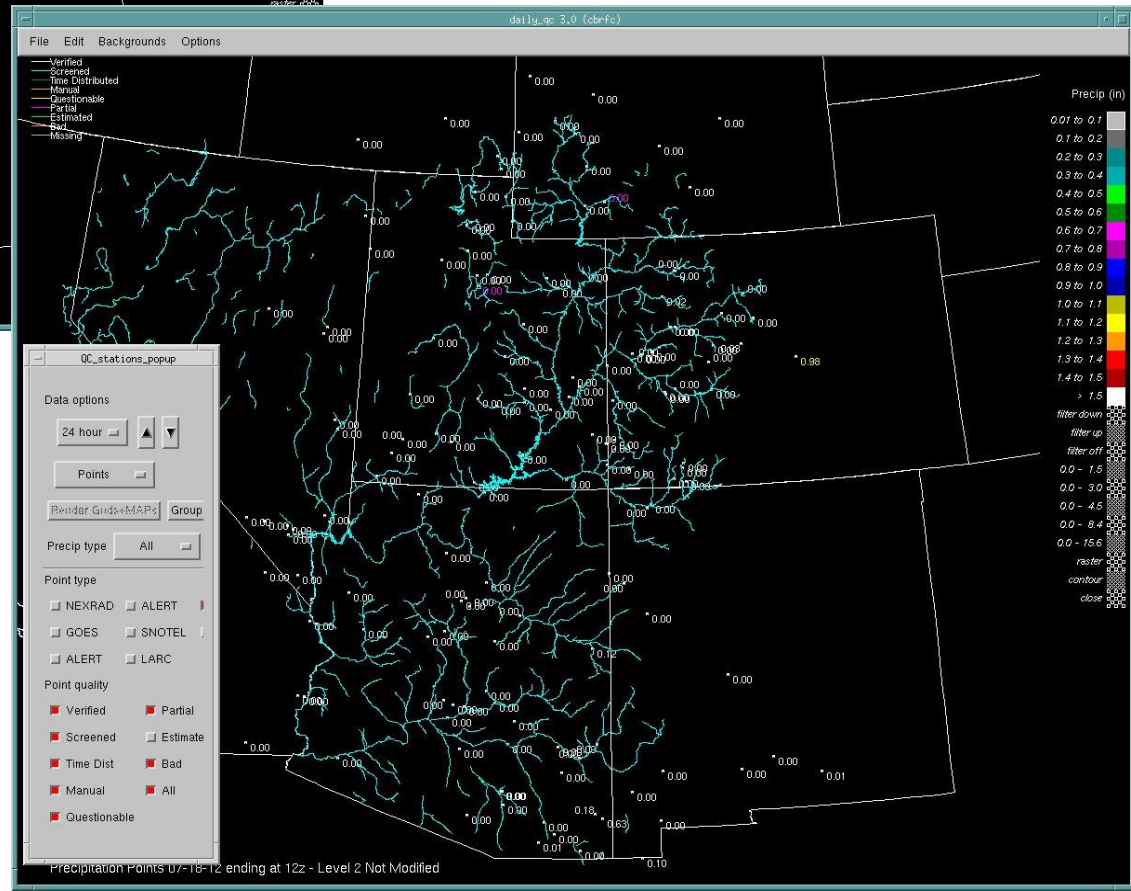

## GOES DCP Precipitation Data

## SNOTEL Precipitation Data

## Cooperator Network

# GOES DCP Temperature Data

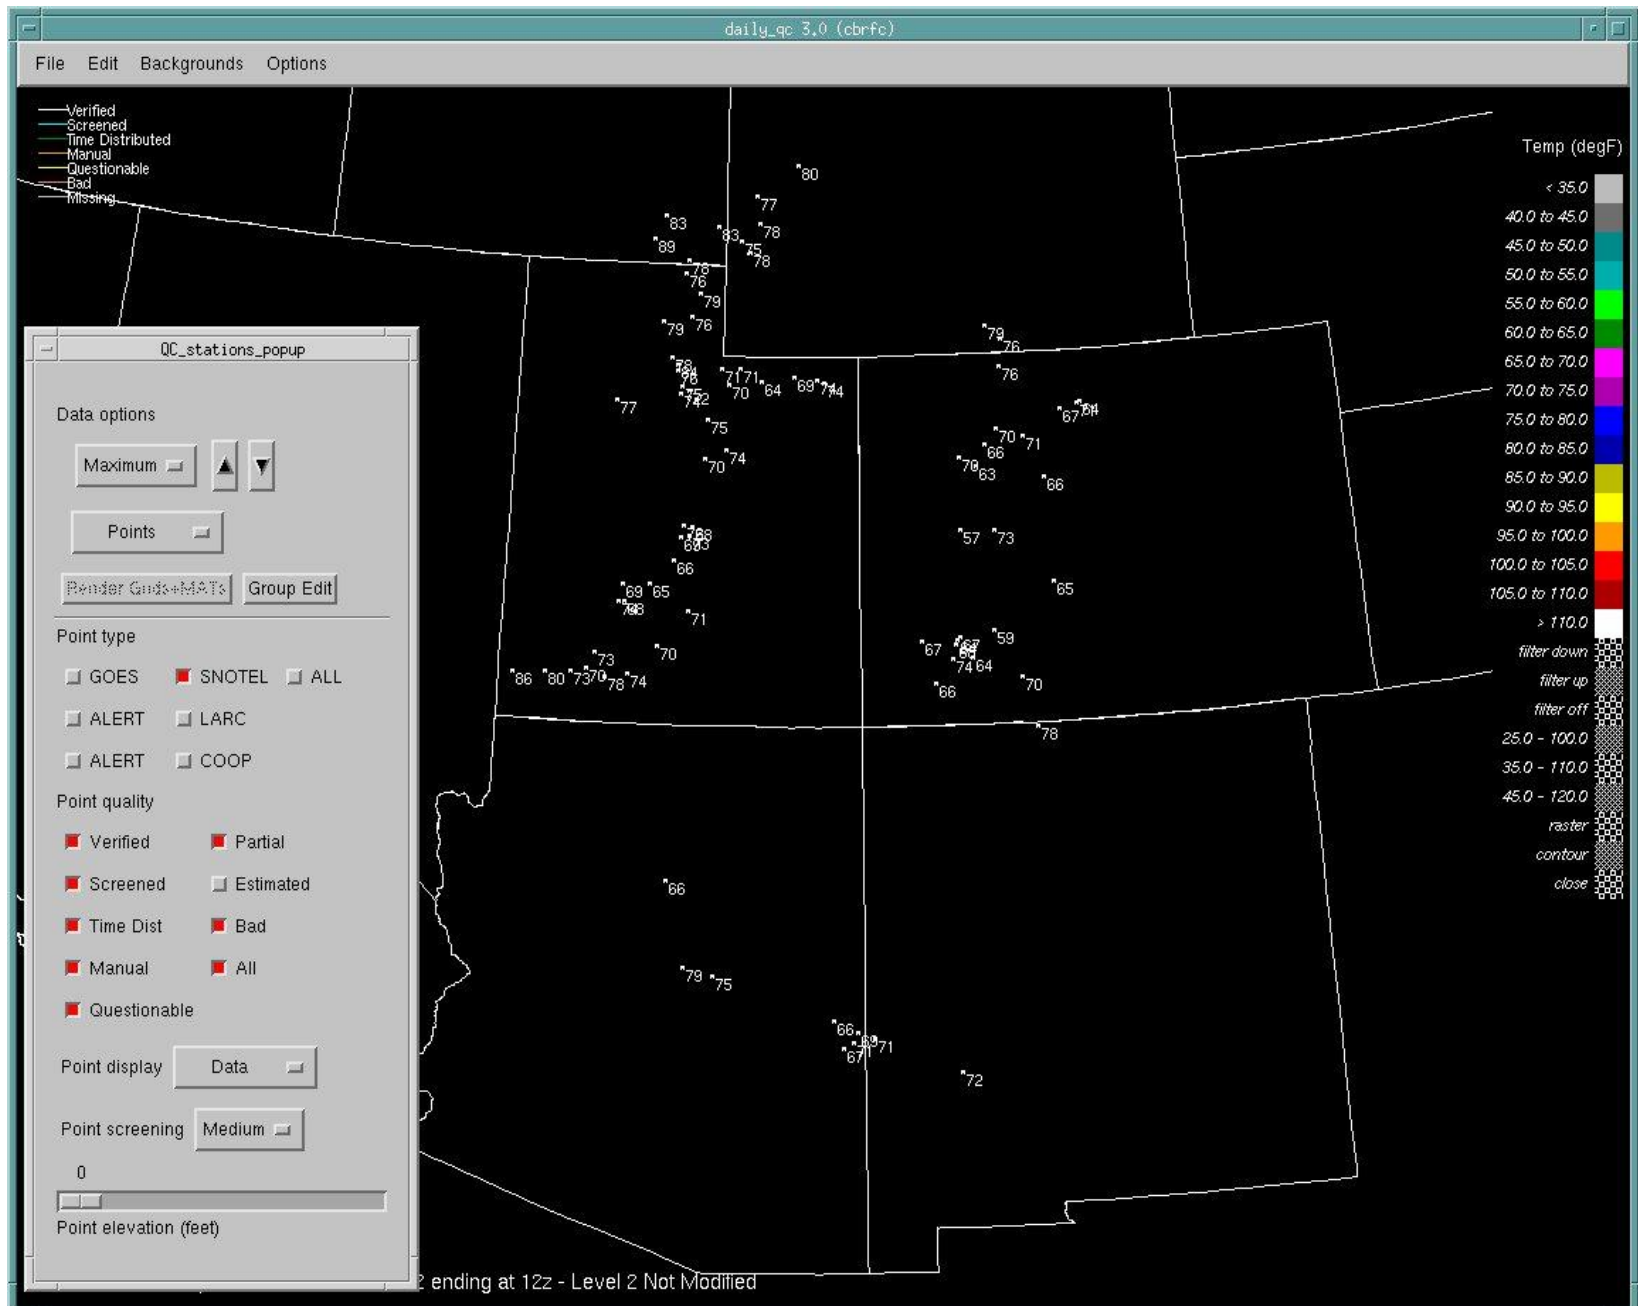

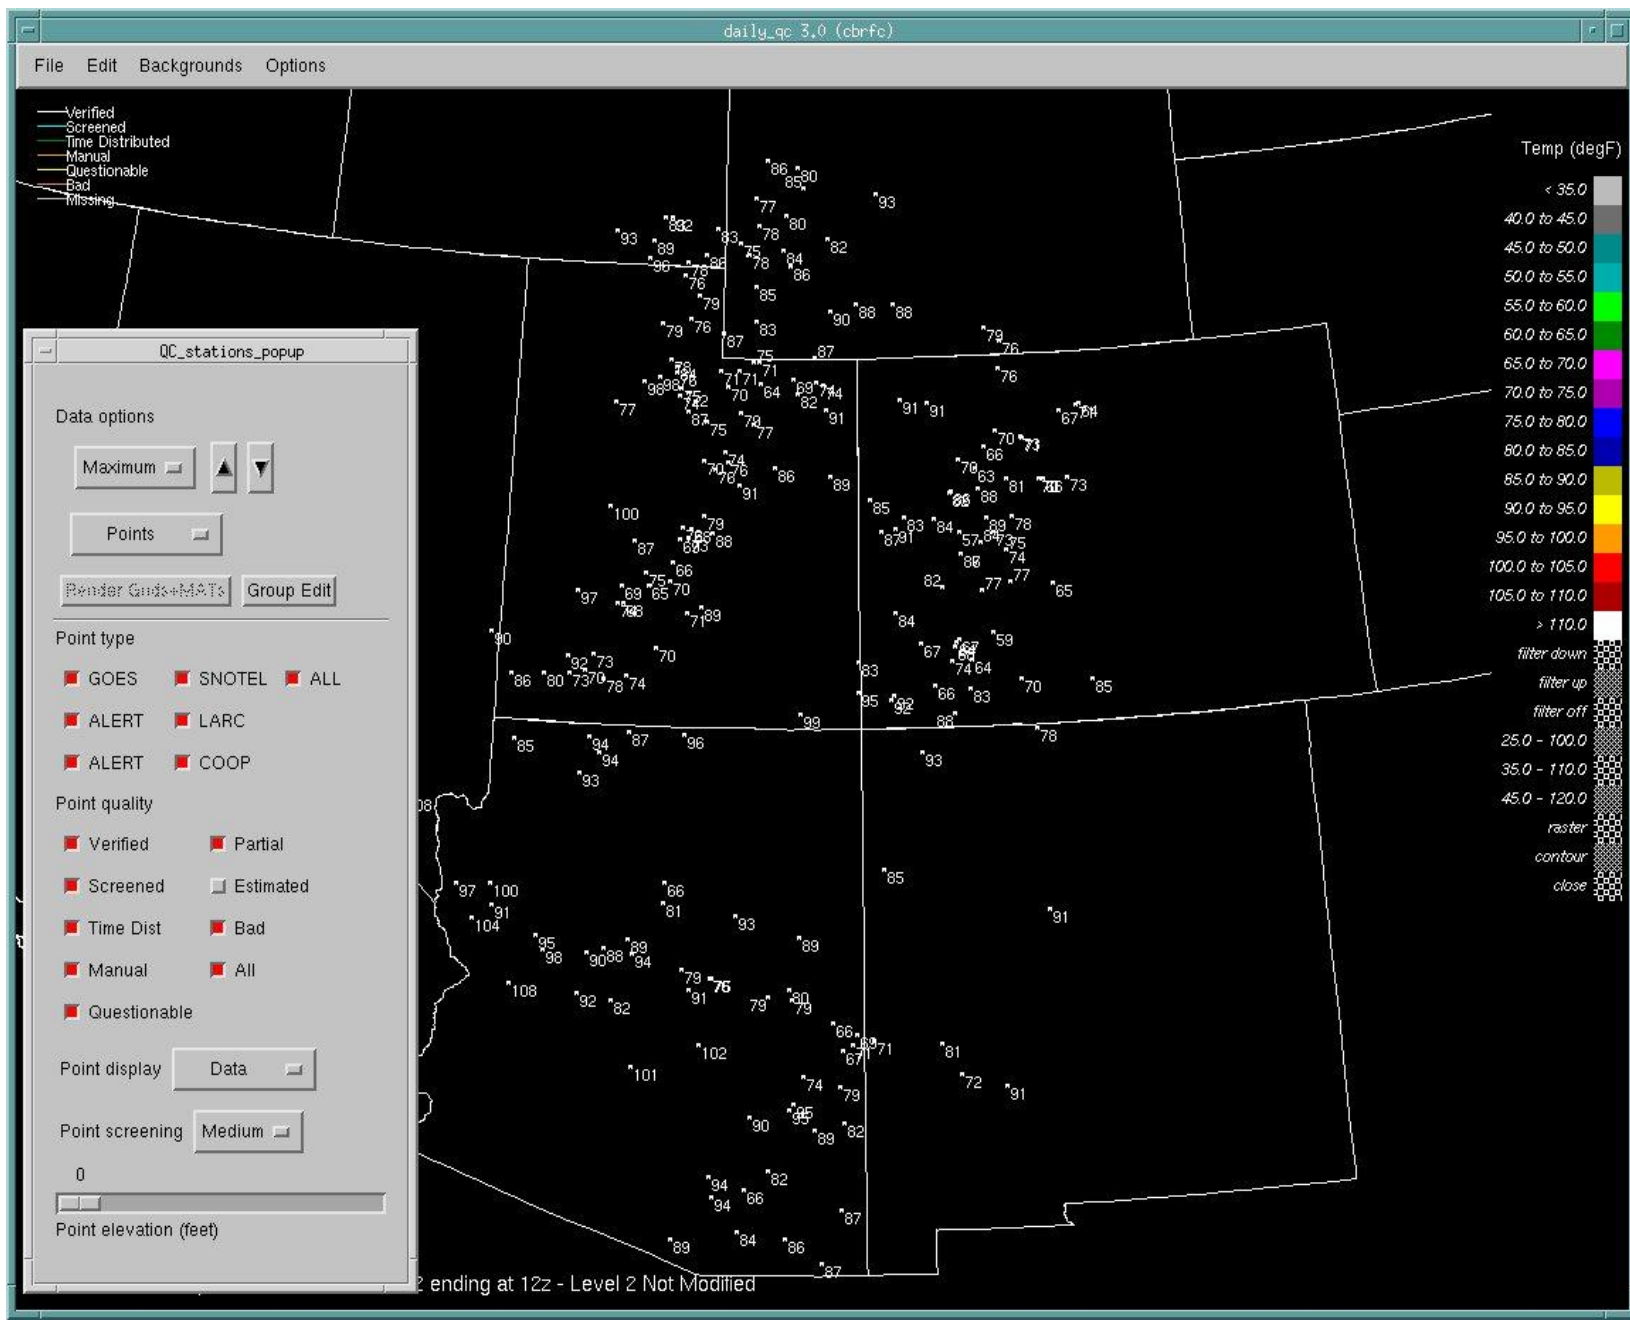

# Cooperator Network Temperature Data

# SNOTEL Network Temperature Data

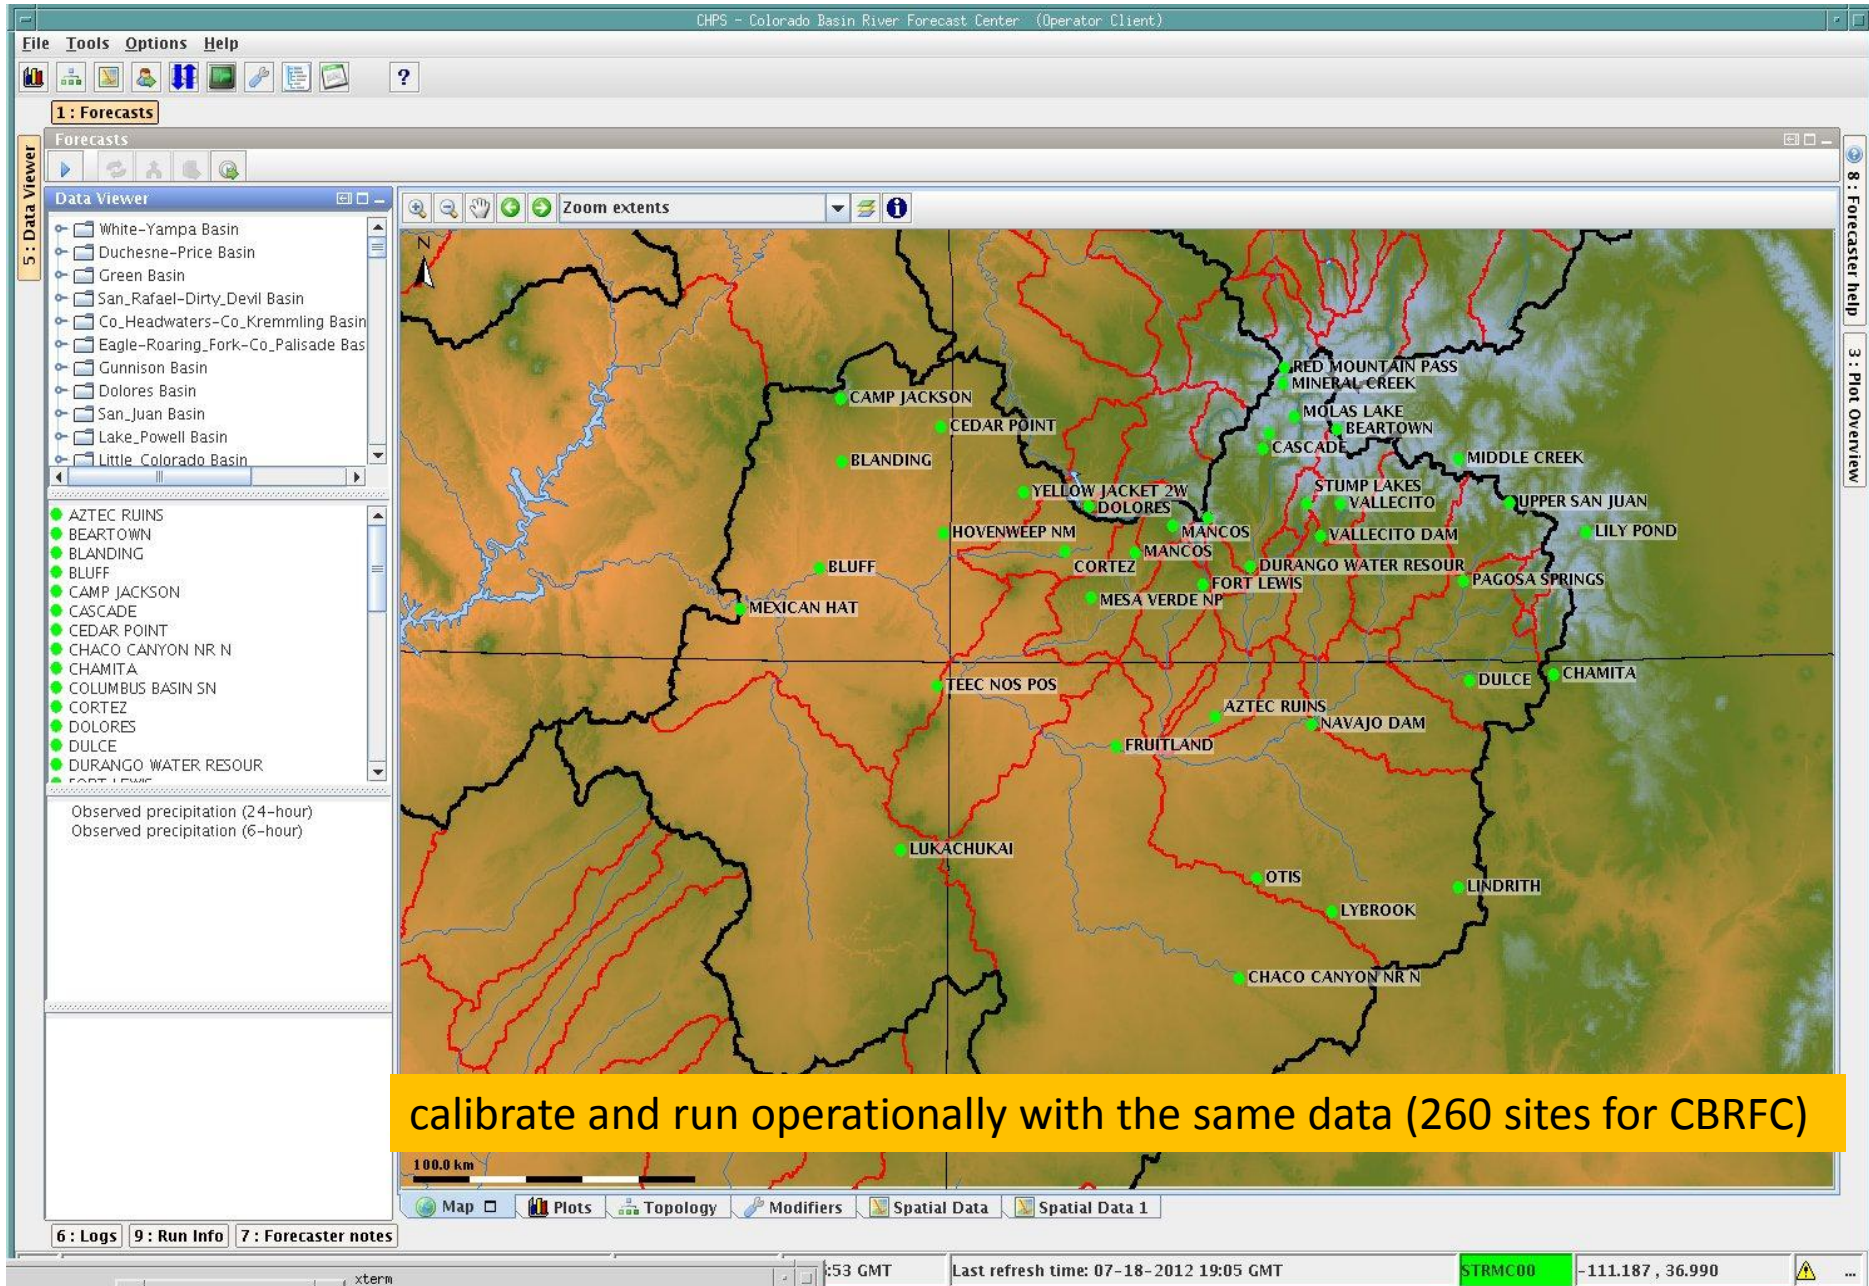

# All Temperature Data Networks

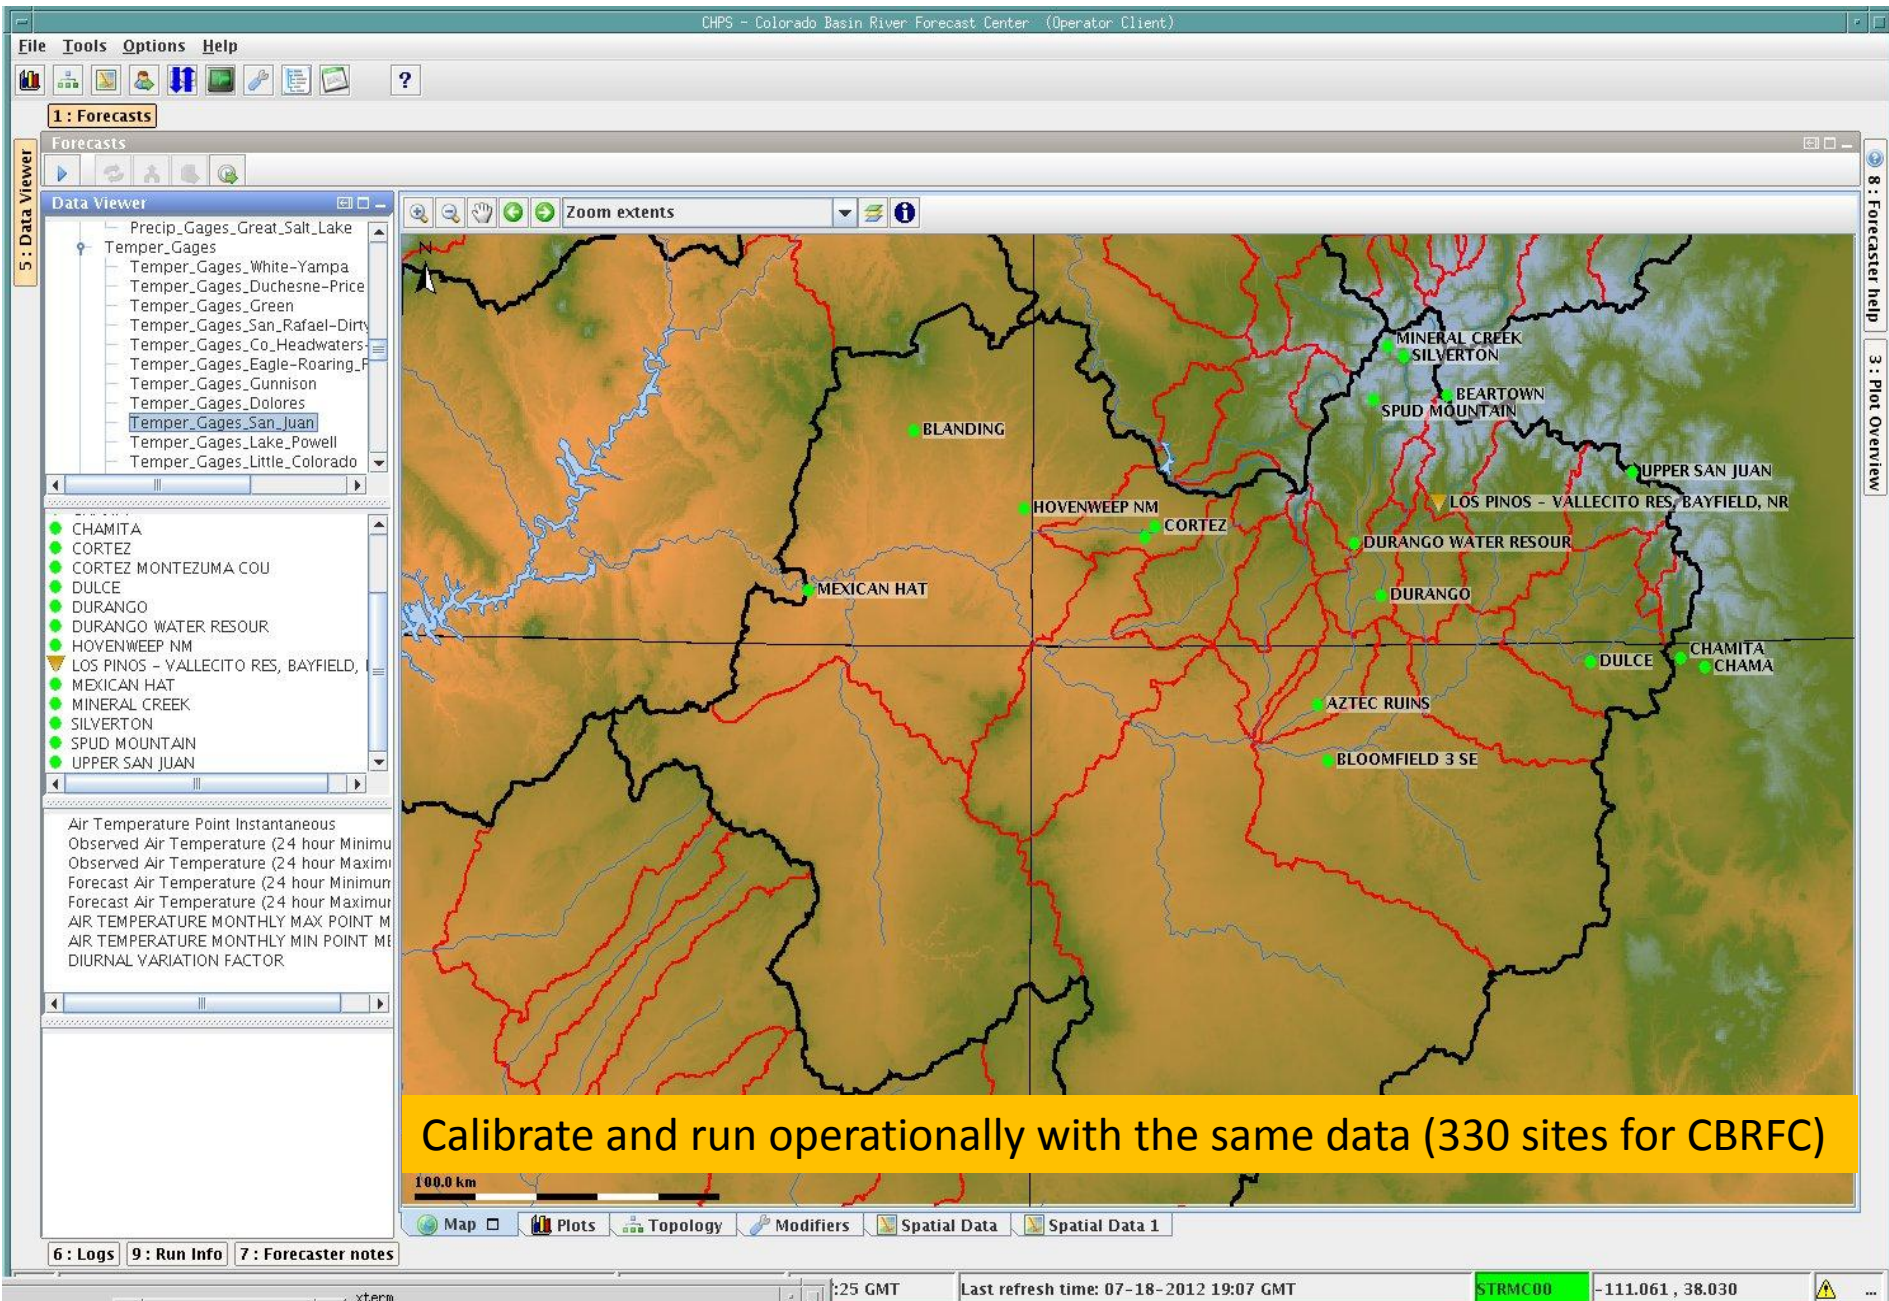

# Precipitation gauge sites used in our model for the San Juan Basin (subset of all available)

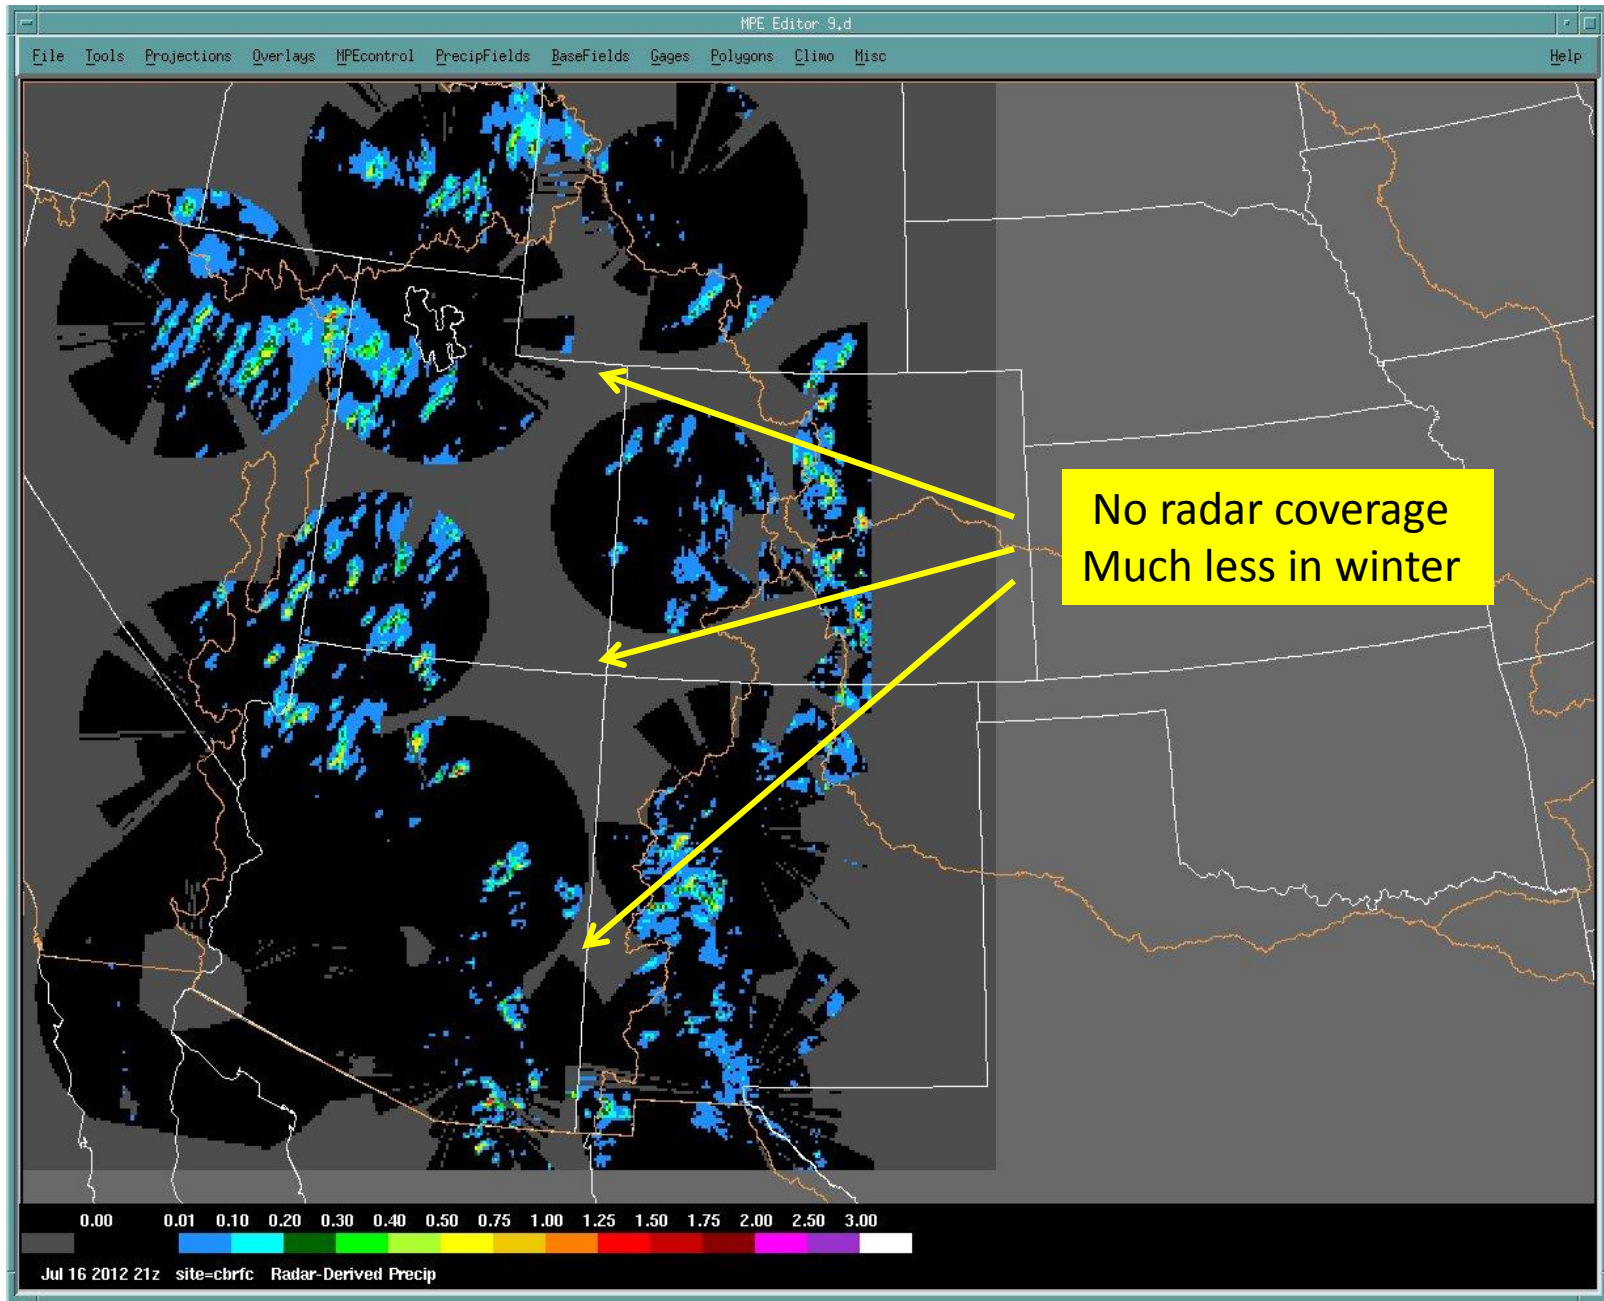

# Temperature sites in the model for the San Juan Basin

## Additional Precipitation Source – NEXRAD Radar Derived Precipitation

Areas where radar precipitation data may be used (rainfall-runoff hydrology dominates) as input to the hydrologic model.

Hourly radar precipitation data is used in southern Utah, Arizona, and New Mexico (1-hour segments)

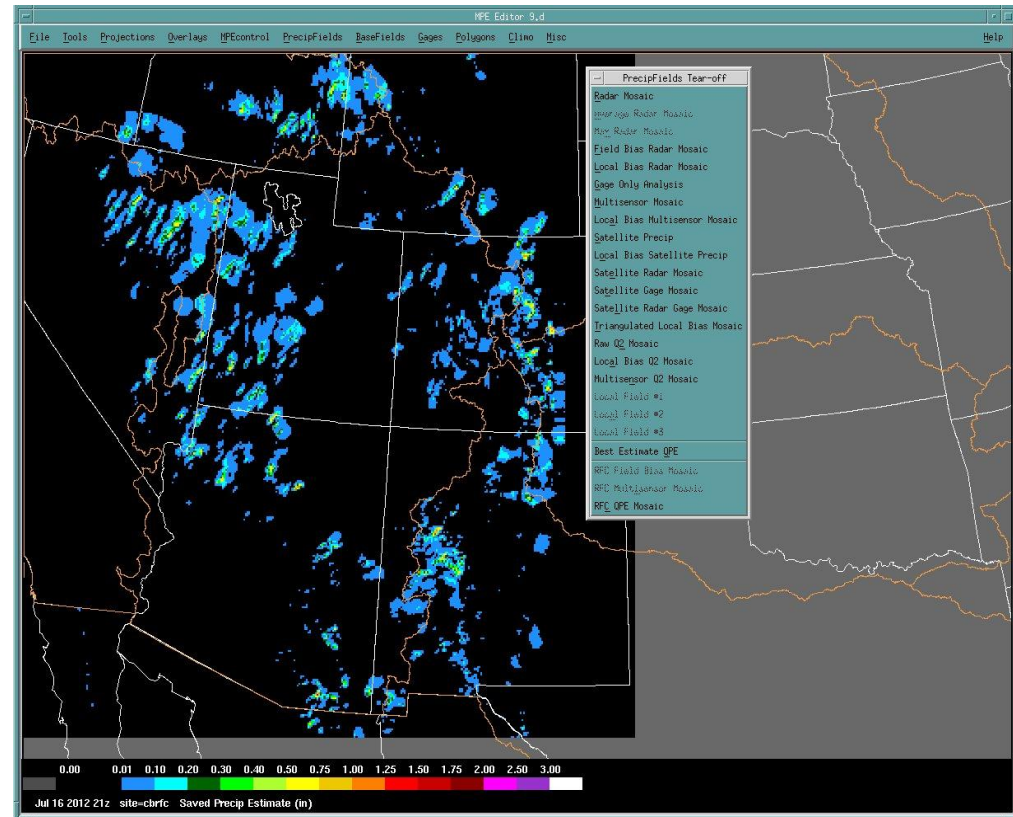

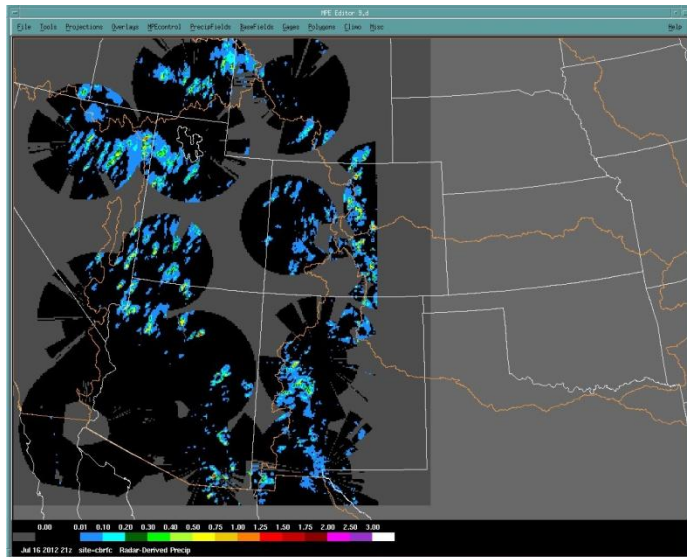

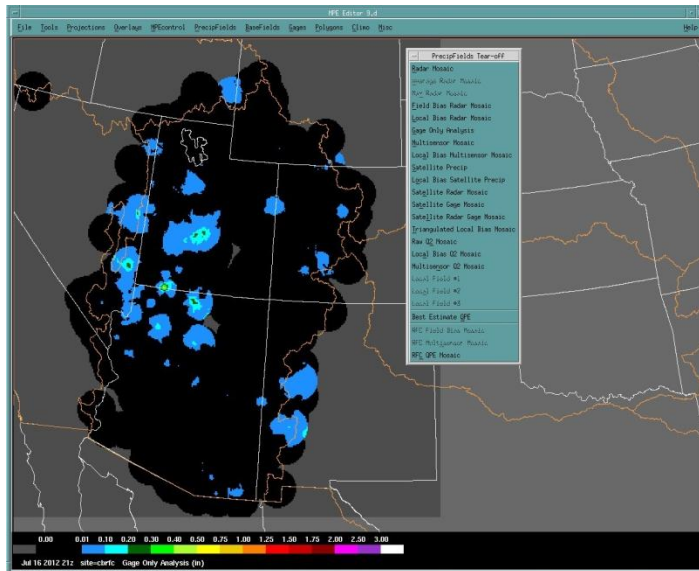

The option exists to use radar precipitation data in northern Utah and Colorado during summer months (6-hour segments)

# Precipitation Source – Hourly Multi-Precipitation Editor (MPE generated Precipitation)

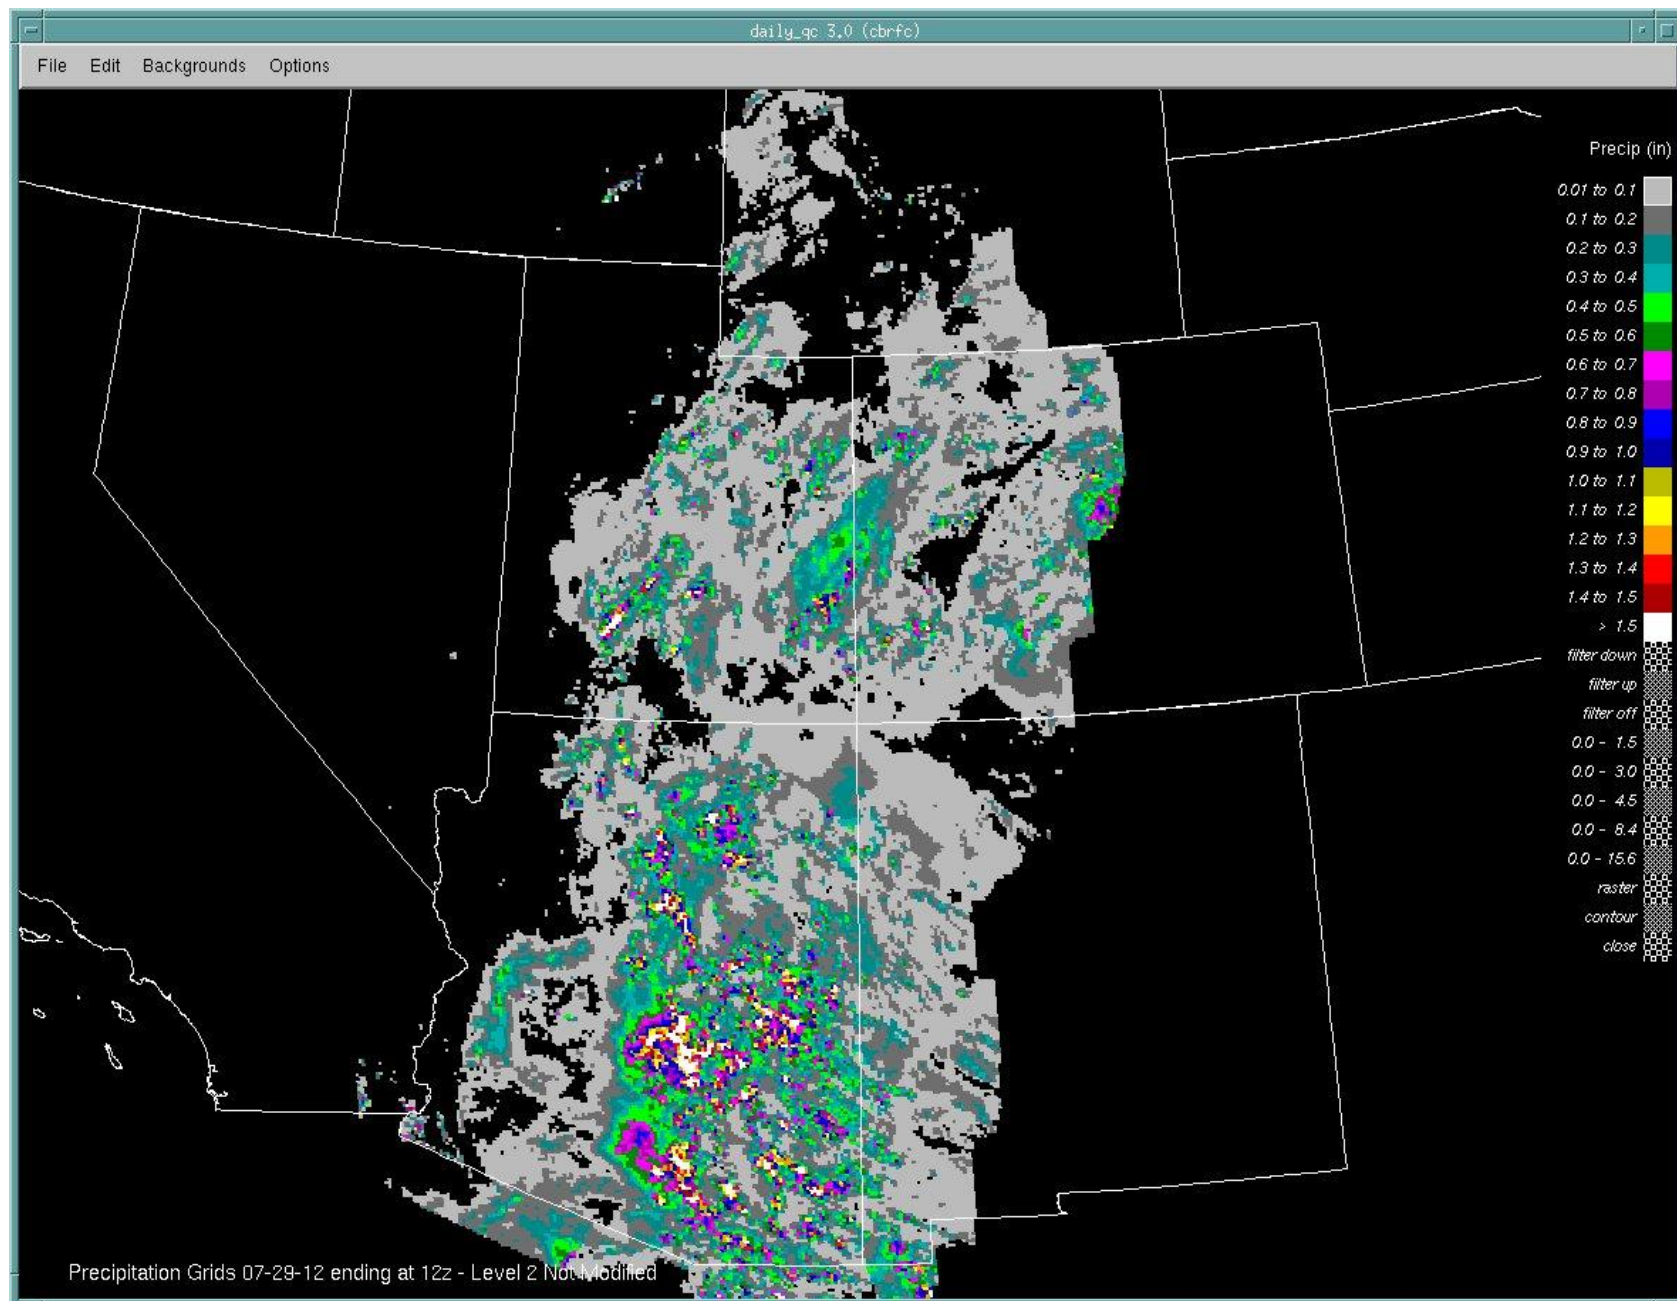

Radar derived precipitation and gage precipitation are combined to generate an hourly gridded product ingested by our hydrologic model

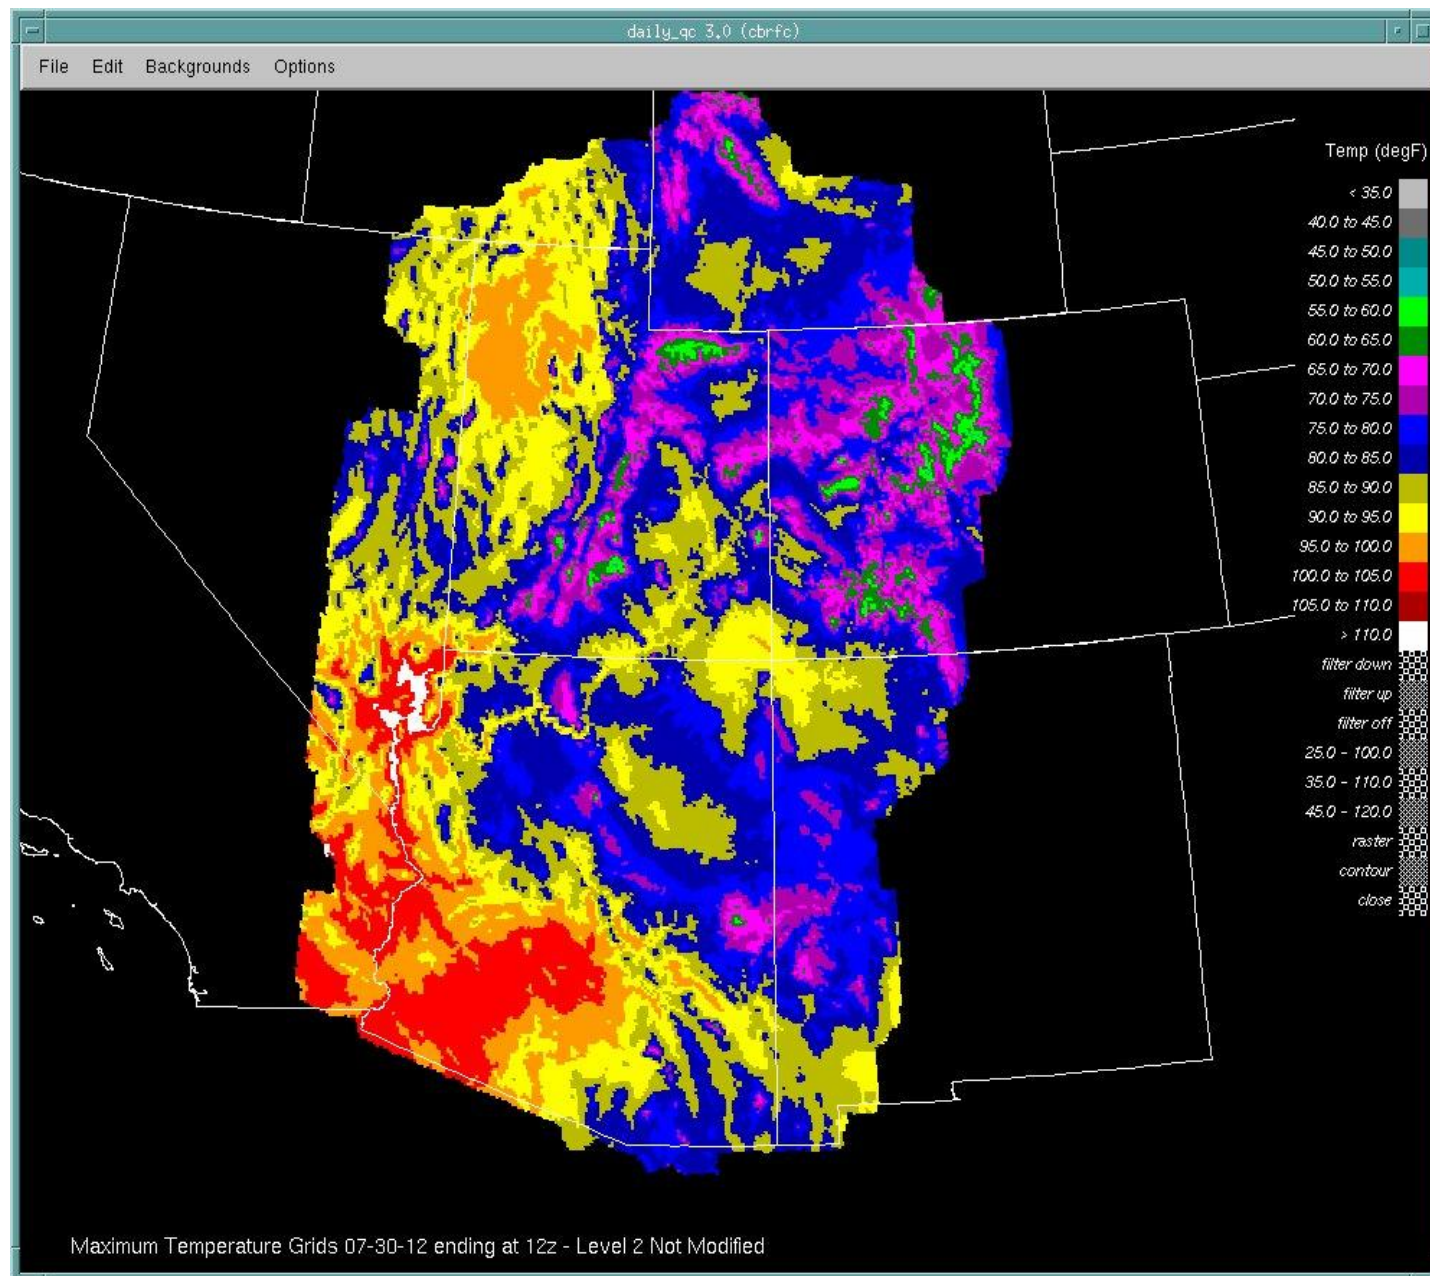

Satellite derived precipitation is available

Goal: Combine all precipitation sources into to a coherent precipitation product

... same goal with temperature

# Goal: Combine all precip & temperature data sources into a coherent product

## Quality Check All Data

- Use all sites all sources
- Meteorological situation
  - Affects gauge performance
  - Expected precipitation patterns

### Measuring Snow Water Equivalent with Heated Tipping Bucket Rain Gauges

Snowflakes melt, trickle into tipping bucket

Evaporation/sublimation from gauge funnel

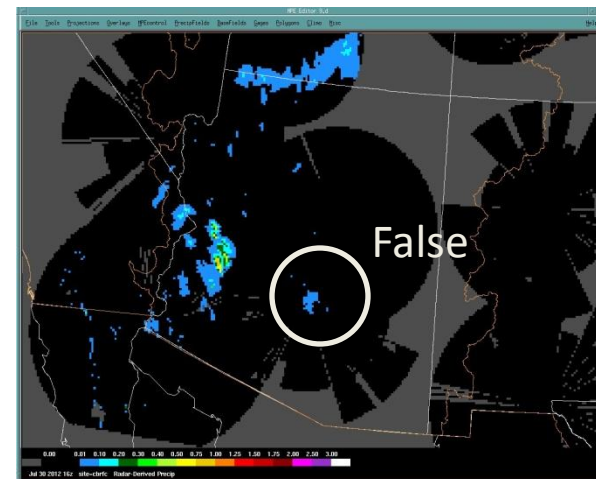

Intense snowfall overflows gauge funnel

©The COMET Program

### Effects of Wind Turbulence Near the Ground on Precipitation and Gauge Catch

# So what gets in the Model (and Forecast) ?

## Quality Check All Data

- Use all sites all sources
- Meteorological situation
  - Affects gauge performance

Convert point 24/6 hour gauge data, to a Mean Areal Precipitation value (MAP).  
Uses only a subset of all sites available.  
Time step = 6 hours.

Convert point data to Mean Areal Temperature (MAT).  
Time step = 6 hours.

Incorporates radar data (MPE) to create a Mean Areal Precipitation (MAP) value.  
Time step = 1 hour.

Observed data (and Forecast precipitation & temperature ) are re-evaluated by forecaster interacting with the model during the daily operational run.

# What is a MAP? Example of Stations used to generate Mean Areal Precipitation

## Dolores – Dolores (DOLC2) Segment (below Rico)

### SAC-SMA Model Sub-Areas

Stations used to compute precipitation & their weighting

Lone Cone (LNCC2) SNOTEL (.17)  
Scotch Creek (SHSC2) SNOTEL (.34)

#### Lower (7067-8500)

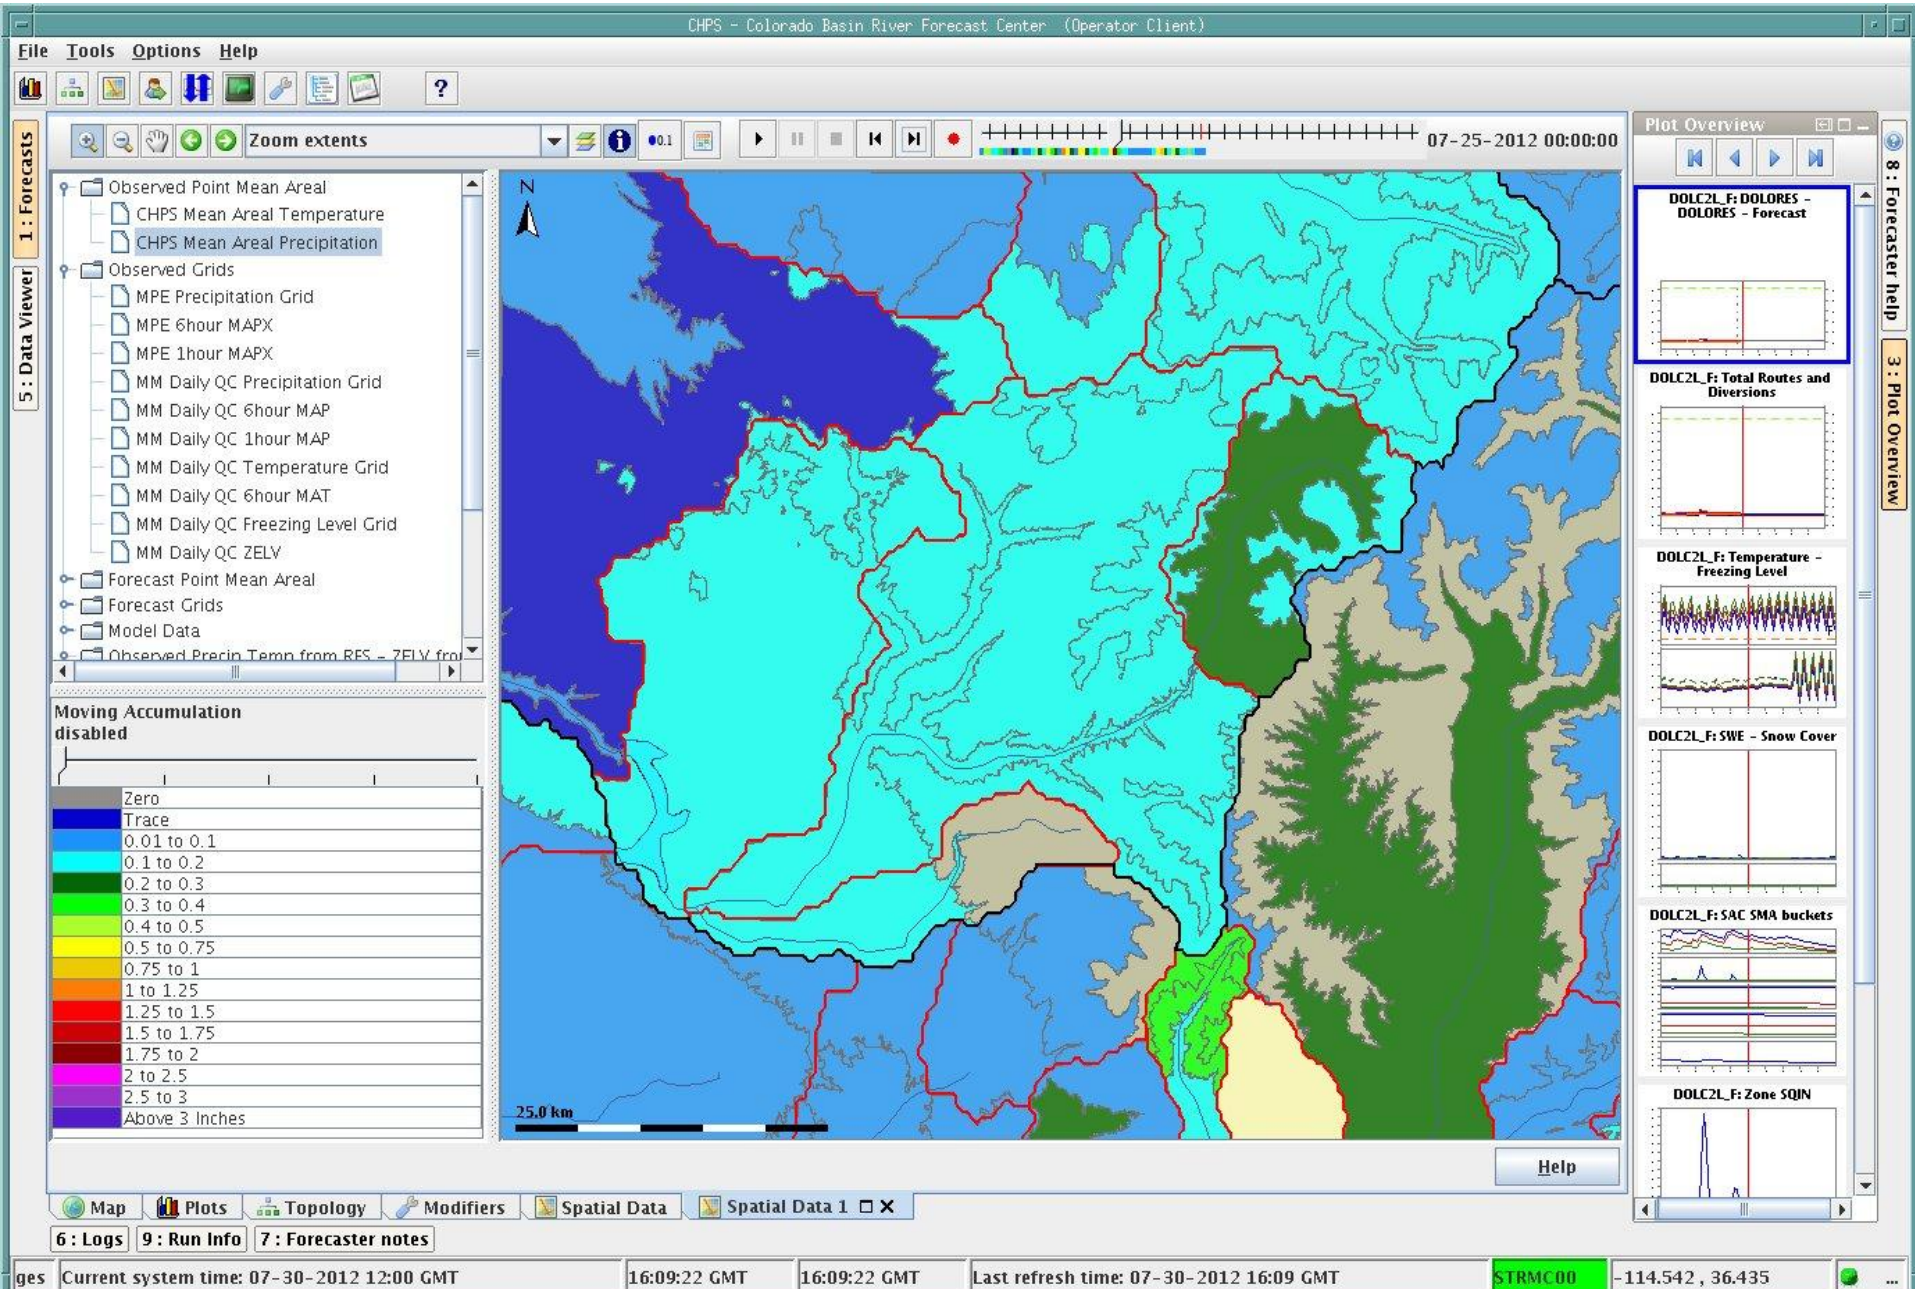

Cortez (CTZC2) Precipitation  
(1.2)

#### Upper (11000-12644)

Lizard Head (LIZC2) SNOTEL (.55)  
El Diente Peak (EDSC2) SNOTEL (.55)

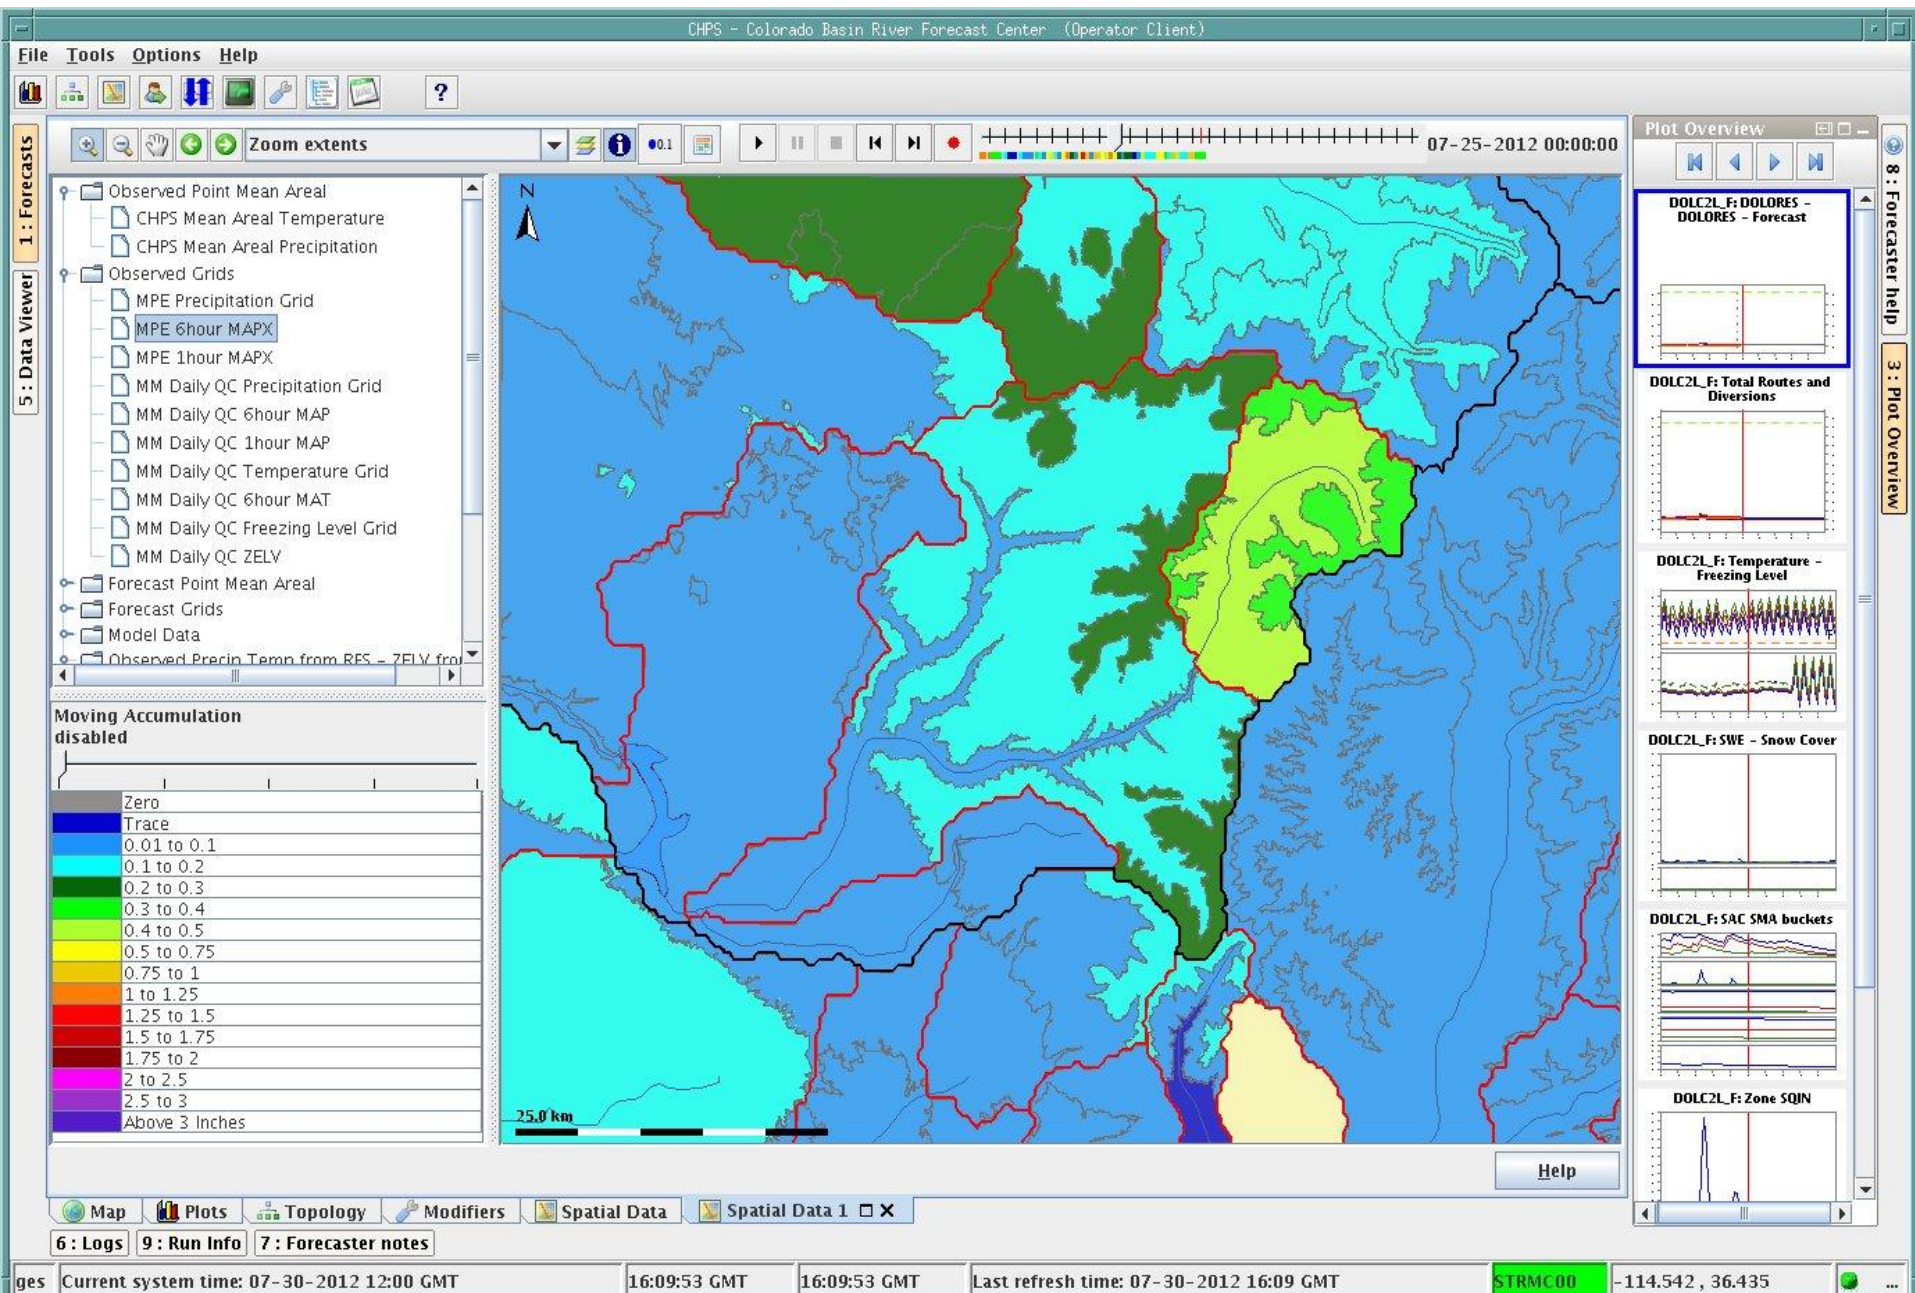

# Operational Model Run 07/25 Noon-6 pm Precipitation for Dolores @ Dolores

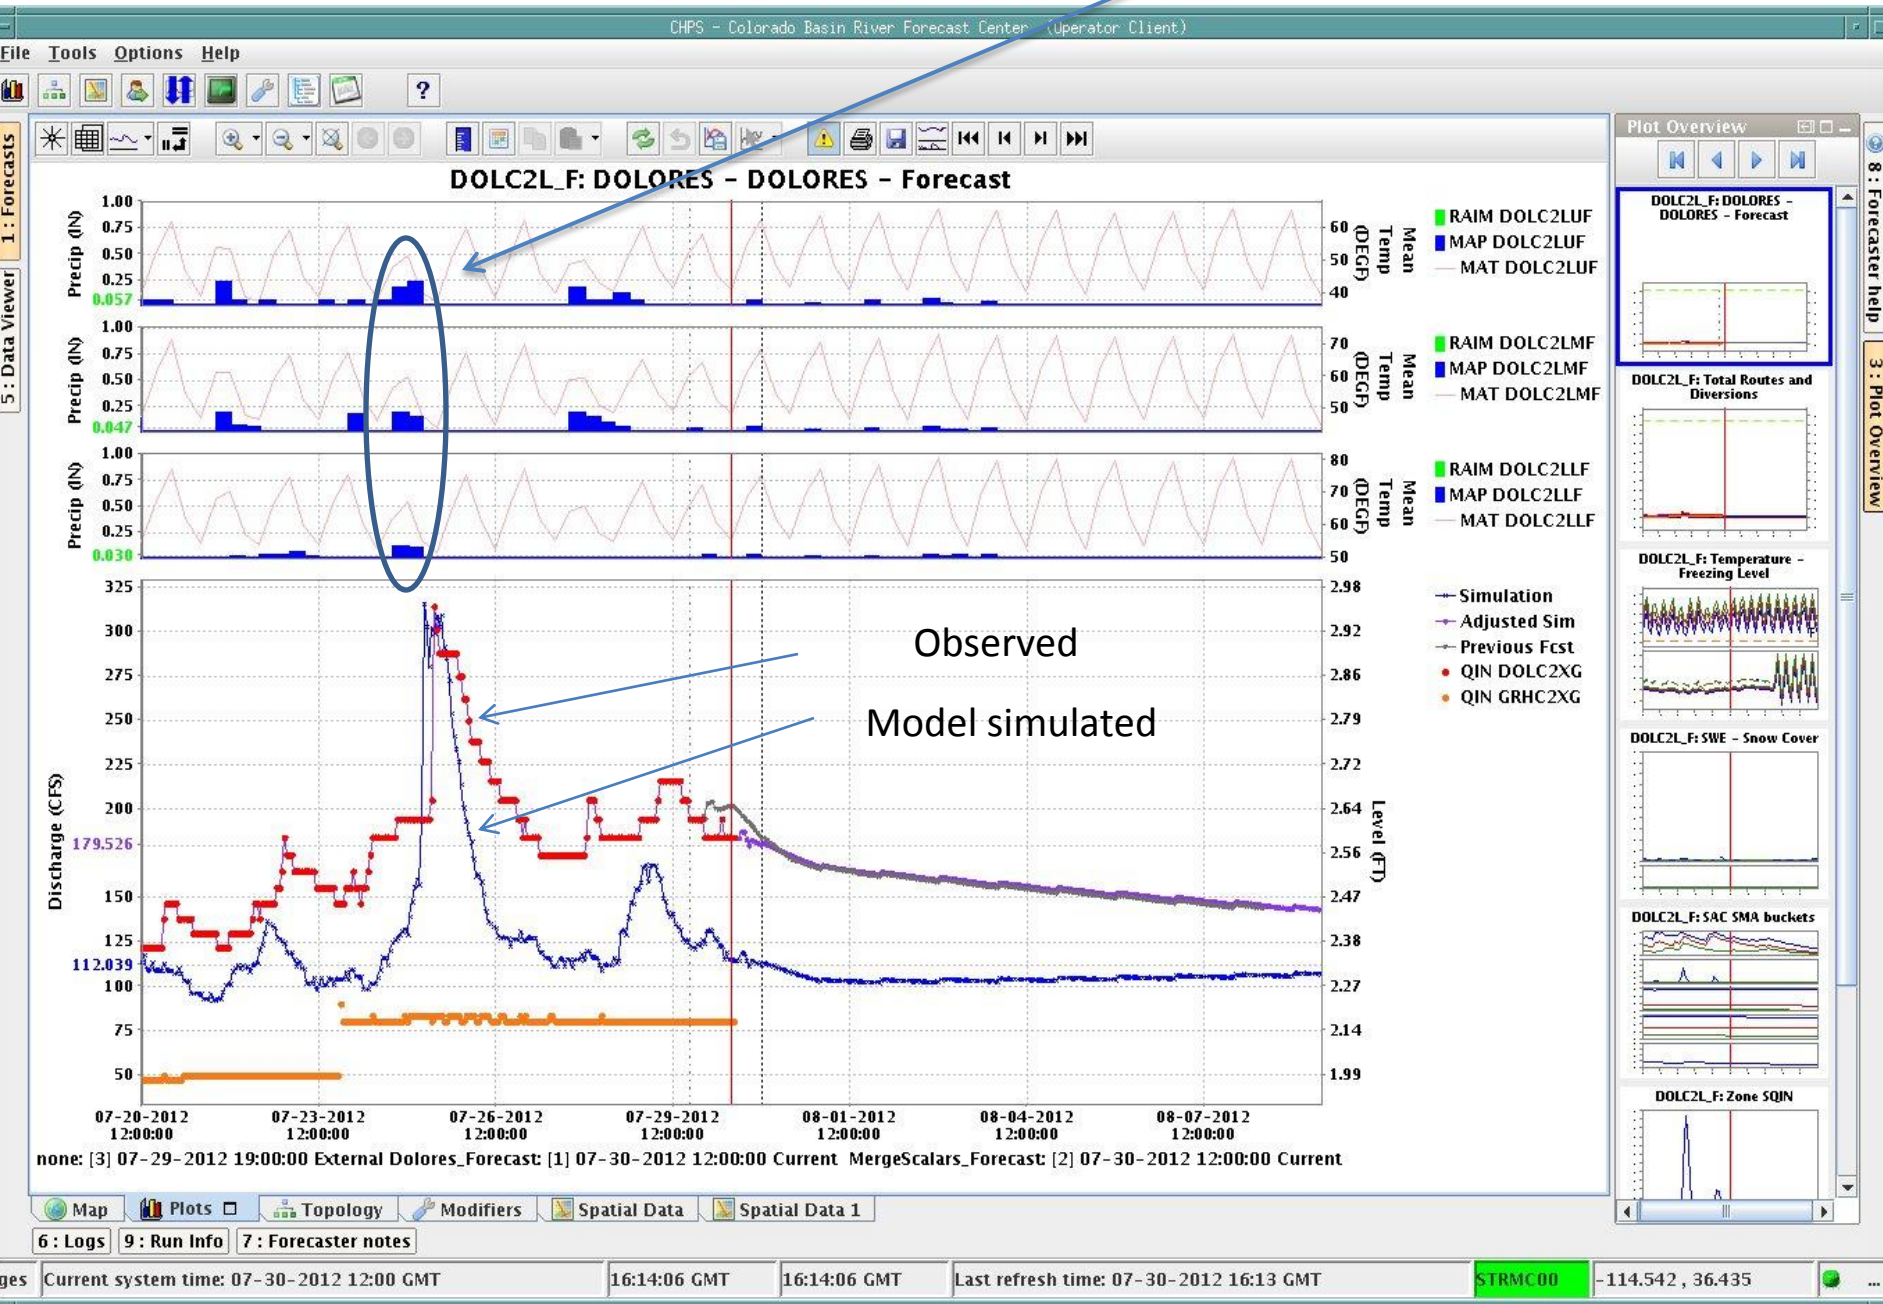

# Operational Model Run 07/25 6pm-Midnight Precipitation for Dolores @ Dolores

# Operational Model Run for Dolores @ Dolores / Precipitation 07/25 Noon-Midnight

6/24 hour gauge data is used to create MAP's in the Great Basin and Upper Colorado Basin

## SUMMARY

Temperature and Precipitation observing networks are critical as they provide direct inputs into our hydrologic models and drive the streamflow forecasts.

- Immediate direct runoff (rainfall-runoff situation)
- Soil moisture states (long term volumes & peaks)
- Snowpack

Maintaining existing networks is critical to our forecast abilities

- Great deal of effort verifying gauge is stable through time.
- Priority given to those sites utilized in calibration / long period of records
  - ***SNOTEL Network our most critical network***
- The loss of any site risks degradation of overall data quality & resulting forecasts
- Surface network especially critical in West due to radar limitations

Consequences of bad (or limited data) are somewhat obvious

- Negatively impact ability to quality control observed data
- Misrepresentation of snowpack (seasonal & peak flow implications)
- Incorrect classification of precipitation types (further impact model states)
- Results: Poor model simulations, missed flood events, poor seasonal forecasts.
